WEEKLY  
REPORT

Week Ending  
August 7, 1965

## U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

PUBLIC HEALTH SERVICE

## INSTITUTIONAL OUTBREAK OF PNEUMONIA

Washington, D. C.

Since July 27 a total of 62 cases of acute pneumonia, 18 of them associated with the isolation of *Klebsiella pneumoniae* (Friedlander's bacillus), have occurred in a large psychiatric hospital in Washington, D. C. There have been eight deaths, most of which have occurred in cases recognized as *Klebsiella pneumoniae* early in the outbreak. Postmortem examinations of six of the fatalities have shown gross pathological findings consistent with a bacterial pneumonia and *Klebsiella pneumoniae* has been isolated from cultures of purulent material obtained from lung specimens of each of these six cases. *Klebsiella*

## INSTITUTIONAL OUTBREAK OF PNEUMONIA

(Continued from front page)

of cases according to age is consistent with the age distribution of the total population of inpatients; there have been 49 male cases and 13 female cases. No widespread minor illnesses have been reported in the hospital as a whole either prior to or during the outbreak of acute pneumonia which appeared to reach its peak in the first week of August.

Apart from the demonstration of *Klebsiella pneumoniae* in 18 cases, there has not been any other etiological agent identified up to the present time. Serological studies of acute and early convalescent serum specimens

from the first 32 patients have been undertaken. So far, employing antigens for histoplasmosis, blastomycosis, psittacosis, Q fever, mycoplasma, and adenoviruses, there has been no suggestion of acute infection with any of these agents.

Epidemiological and laboratory studies are continuing. (Reported by Dr. Dale C. Cameron, Hospital Superintendent, Dr. Murray Grant, Director of Public Health, District of Columbia, and a team of CDC epidemiologists working with the staff of the Hospital and the Department of Public Health.)

## RABIES IN ANIMALS AND MAN - 1964

## Annual Surveillance Summary

There were 4,784 laboratory confirmed cases of animal rabies during 1964, which is 20 percent more than in 1963. Substantially larger numbers of reports of fox and skunk rabies accounted for this increase.

The incidence of animal rabies had dropped steadily from 1946 to 1960, but since 1961 this trend has been re-

versed (Figure 1). The distribution of animal rabies throughout the U. S. is shown in Figure 2. Only 4 States recorded no cases of animal rabies, while 19 States reported a reduction and 28 States, an increase. The incidence of animal rabies in the U. S. from 1953 to 1964 is detailed in Table 1.

Table 1

## INCIDENCE OF RABIES IN THE UNITED STATES BY TYPE OF ANIMAL - 1953-1964\*

## RABIES IN ANIMALS AND MAN-1964 - Annual Surveillance Summary

*(Continued from page 266)*

Dog rabies declined to the lowest level yet recorded, being only 10 percent of the total. Just under one-third of the dog rabies occurred in the four States on the U.S.-Mexican border. Another 26 percent occurred in the four contiguous States of Kentucky, Tennessee, Missouri, and Illinois. These eight States have accounted for 62 percent of the dog rabies reported in 1963 and 58 percent in 1964.

Wildlife rabies accounted for 75 percent of the total animal rabies in 1964, foxes and skunks giving rise to over 82 percent of this subtotal. There has been a substantial increase in the incidence of bat rabies since the first confirmed case in 1953 (Figure 3). A total of 35 States reported one or more cases of bat rabies during the year; Mississippi reported 67, the largest number from any one

State prior to 1964. For 2 years Mississippi had been free of animal rabies.

One human rabies death occurred in a 10-year-old Minnesota boy, following the bite of a rabid skunk (MMWR, Vol. 13, No. 38). This one case of human rabies had a short incubation period of 20 days and despite 14 doses of duck embryo vaccine, starting on the day of occurrence, the patient died. This is not considered to be a case of vaccine failure as experience has shown that rabies vaccine is usually effective in preventing rabies only when it is given immediately after exposure and the incubation period exceeds 30 days.

*(Reported by the Zoonoses Surveillance Unit of CDC.)*

Figure 3.  
CASES OF RABIES IN BATS - 1953-1964

## EPIDEMIOLOGIC NOTES

## BAT RABIES – Iowa

On the evening of June 8, 1965, a four-year-old boy was riding his tricycle down the driveway of his aunt's house when a bat fell or swooped from a nearby tree. As this happened a car turned into the driveway and the bat, swerving to avoid it, hit the boy on the back and clung to his T-shirt. The boy grabbed the bat and flung it on to the pavement, stunning it. The occupants of the car got out; since the bat was still alive, they killed it using a stick. The City Health Department was called and the bat, described as being grey and brown in color, with a body 3 to 4 inches long and with a wingspan of about 14 inches, was removed for laboratory tests.

The boy was taken to a physician who found two superficial scratches on the boy's back in the lower thoracic region. These scratches were washed with hydrogen peroxide and hyperimmune rabies serum was given.

On June 10 the Iowa State Hygiene Laboratory reported that brain, brown fat, and salivary gland tissues from the bat were all positive for rabies, using the fluorescent antibody technique. The same day the physician gave the boy the first dose of a duck embryo rabies vaccine series.

No other person had had any direct contact with the infected bat. Other bats had been seen flying in the vicinity of the house the evening the boy was attacked. There is a drainage tunnel which goes under the streets nearby where bats are said to harbor, but none were found in this tunnel when it was inspected. Further investigations are proceeding.

*(Reported by Ralph H. Heeren, M.D., State Epidemiologist, and Carl Zymet, DVM, Asst. Public Health Veterinarian, Iowa State Health Department.)*

## CUTANEOUS ANTHRAX – South Carolina

A case of cutaneous anthrax involving a 29-year-old U.S. Customs inspector has been reported from Charleston, South Carolina. On July 27 the inspector first noticed a small pimple on his right forearm and experienced headache, stiff neck, and malaise. A few days later when the pimple began to itch, it drew attention to several smaller erythematous papule-like lesions several centimeters below the initial pimple. On August 1, the patient squeezed the pimple, which caused a small amount of thin bloody discharge. Later that day he noted some firmness around the affected area and developed chills and fever to 100 degrees. The following day the patient saw his private physician.

By this time there was a thin brown crust on the forearm, one centimeter in size, with a five millimeter ring of

erythema and some surrounding edema. Lymphangitis extended from the lesion half-way up the upper arm. Several firm, pea-size nodules were palpated along the route of the lymphangitis, but epitrochlear, axillary, and cervical lymphadenopathy were not present.

Although the patient denied any known contact with animals or plants, he said that he had inspected bales of imported wool as recently as July 15. He vaguely recalls being bitten by a fly in the area of the lesion, possibly while working on July 15. On the basis of this history the physician diagnosed cutaneous anthrax and treated the patient with 750 mg. of tetracycline given every 4 hours. During the next few days the patient's systemic symptoms disappeared. The lesion itself did not show any significant changes and a black eschar was never noted.

Although the prolonged incubation period and characteristics of the lesion were not typical of cutaneous anthrax, the clinical story and the contact with wool are consistent with the diagnosis. Laboratory studies have failed to confirm the diagnosis but the patient had had substantial antibiotic therapy prior to the collection of laboratory specimens.

*(Reported by Dr. G. E. McDaniel, Director, Division of Disease Control, South Carolina State Board of Health; Dr. E. K. Aycock, Charleston County Health Department; and the Staff of the Investigations Section of CDC.)*

## ANIMAL ANTHRAX – North Dakota

An outbreak of anthrax in cattle near the Turtle River in Grand Forks County, North Dakota has been reported. Nineteen head of cattle on six separate farms have died. Three of these cases have been confirmed in the laboratory. The first death occurred June 15, and the last known death on July 31. All cattle affected have been on pasture receiving no supplemental feed with the exception of salt. Evidence points to contaminated soil as the route of transmission. No documented history of anthrax exists for the area, although one individual recalled a diagnosis of anthrax in a horse in 1929 on one of the involved farms.

No human cases have been reported. As two of the animals were found dead in the River, some concern was felt for a camp of diabetic children downstream from the area; penicillin was administered, as a prophylactic, to these children.

Samples of soil, salt, and river water are now being studied in the laboratory.

*(Reported by Robert Eelkema, D.V.M., M.D., Infectious Disease Consultant, School of Medicine, University of North Dakota, Grand Forks; Dr. James R. Amos, State Health Officer; Mr. Kenneth Mosser, North Dakota State Epidemiologist, Bismarck; and a team from CDC.)*
